Abstract. *Background/Aim:* Breast cancer cell lines consist of bulk tumor cells and a small proportion of stem-like cells. While the bulk cells are known to express a distinct combination of Eph receptors and ephrin ligands, the transcript profiles of stem-like cells in these cell lines have not been adequately characterized. The aim of this study was to determine Eph receptor/ephrin ligand profiles of cancer stem cells specific to a triple negative breast carcinoma cell line. *Materials and Methods:* The normal breast cell line MCF10A and the invasive breast carcinoma cell line MDA-MB-231 were used to isolate CD24⁺/CD24⁻ cell populations. The profiles of Eph receptors and ephrin ligands were determined by real-time PCR and the relative abundance in bulk and stem cells were compared. *Results:* Based on the mean ΔCT values, the descending order of abundance was as follows. Ephrin-A5 > EPHA2 > (EPHA8, EPHB2) > ephrin-B2 > (EPHA7, EPHB4, ephrin-A4) > ephrin-A3 > ephrin-A1 > (EPHB3, ephrin-B1) > EPHA4 > EPHA1 > EPHA10. EPHA6 and ephrin-A2 transcripts were not detectable in stem cells from either cell line. The expression of EPHA4, EPHA7, EPHA8, and ephrin-A5 in MDA-MB-231 stem cells was up-regulated by 12, 20, ~500, and 6.5-fold respectively. *Conclusion:* The up-regulation of transcripts for EPHA8 and its cognate ligand, ephrin-A5, in the stem cells isolated from MDA-MB-231, suggest their involvement in the invasiveness of this cell line. Based on literature reports, we

propose the role of EPHA8 and ephrin-A5 in MDA-MB-231 stem cells via the PI3K-AKT-mTOR pathway.

Breast cancer is the leading cause of cancer-related mortality among women globally. According to breast cancer statistics, the majority of breast cancer-related deaths are attributed to the development of secondary tumors that arise *via* metastasis (1). Triple-negative breast cancer (TNBC) is the most aggressive subtype and accounts for approximately 10-15% of all cases (1). Accumulating evidence suggests that a small subset of tumor-initiating cells, collectively referred to as breast cancer stem-like cells (BCSCs), are potential drivers of the metastatic progression of breast cancers (2, 3). BCSCs are a distinct subset of tumor cells that display the capacity for self-renewal, differentiation, recapitulation of tumor cellular heterogeneity, and tumor cell metastasis (4-6).

Erythropoietin-producing hepatocellular carcinoma (EPH) receptors and their cognate ephrin ligands constitute the largest family of receptor tyrosine kinases (RTKs). Our laboratory has previously demonstrated that the aberrant expression of EPH receptors and ephrin ligands contributes to the invasive characteristics of breast carcinoma cells (7-9). In the human proteome, there are nine Eph-A receptors (EPHA1-EPHA8 and EPHA10) that bind with high affinity to five GPI-linked ephrin-A ligands (ephrin A1- ephrin A5) (10). Similarly, there are five Eph-B receptors (EPHB1-EPHB4, and EPHB6) that bind with high affinity to three ephrin-B ligands that are structurally defined by a single transmembrane-domain and a cytoplasmic PDZ binding domain (11). Eph receptors have prototypical RTK modular architecture as displayed by the highly conserved extracellular and cytoplasmic domains (12). Eph-ephrin interactions can activate intracellular signaling cascades via forward, reverse, and lateral cis mechanisms, which modulate cell adhesion and repulsion dynamics (13). Interestingly, the distinctive spatiotemporal expression patterns of EPH/ephrin membrane proteins in epithelial cells

This article is freely accessible online.

Key Words: Breast carcinoma, stem cells, stem-like cells, triple-negative breast cancer cells, Eph receptors, ephrin ligands, CD44⁺/CD24⁻ cells, MDA-MB-231 cells.

can either promote or suppress tumorigenicity (14). In the context of breast cancer, EPHA2 is expressed at low levels in non-tumorigenic human breast epithelial tissue; however, in 60-80% of human breast carcinomas EPHA2 is overexpressed while its preferred ligand, ephrin-A1, is down-regulated (15) substantiating EPHA2 ligand-independent signaling as a mechanism for breast cell tumorigenesis. More recent data suggest the disruption of the Eph/ephrin signaling may also contribute to the acquisition of the breast stem-like phenotype (16). Studies have shown that BCSC self-renewal and differentiation are orchestrated by cells that inhabit the stem cell niche, which employ Eph-ephrins to facilitate cell-cell and cell microenvironment communication thereby implicating the Eph-ephrin system as potential regulators of both stem cell and cancer stem cell dynamics.

Therefore, in order to investigate the potential role of EPH-ephrins in the breast cancer stem cell niche, mRNA expression profiles were established for all detectable EPH-ephrins transcripts in the CD44⁺/CD24⁻ and CD44⁺/CD24⁺ cells from two phenotypically distinct breast epithelial cell lines: non-tumorigenic breast epithelial cells (MCF10A) and invasive, triple-negative breast carcinoma cells (MDA-MB-231). The comparative analysis of EPH/ephrin transcripts in MCF-10A and MDA-MB-231 from bulk (CD44⁺/CD24⁺) and tumor-initiating (CD44⁺/CD24⁻) cell populations indicated distinct expression profiles and suggested an important role for EPHA8 and ephrin-A5 receptor/ligand pair in modulating the invasive phenotype of MDA-MB-231.

Materials and Methods

Cell culture method. MCF10A (nontumorigenic breast epithelial cells) and MDA-MB-231 (triple-negative, invasive breast carcinoma) cell lines were obtained from American Type Culture Collection (Manassas, VA, USA). MCF-10A cells were maintained in 1:1 DMEM:F12 medium (Thermo Fisher Scientific, Grand Island, NY, USA) supplemented with 5% horse serum and 0.1 µg/ml Cholera Toxin, and 500 ng/ml hydrocortisone (Sigma-Aldrich, St. Louis, MO, USA), 10 ng/ml EGF and 10 µg/ml of insulin (Thermo Fisher Scientific). MDA-MB-231 cells were maintained in DMEM medium (Thermo Fisher Scientific) supplemented with 10% horse serum from Sigma-Aldrich. The culture medium was supplemented with 5,000 U/ml of penicillin/streptomycin (Sigma-Aldrich), and the cells were grown in a humidified chamber with 5% CO₂ at 37°C.

Cancer stem cell separation. The cells (~2×10⁷) were rinsed in PBS and suspended in cold 1X MagCelect Plus Buffer from the MagCelect CD44^{high} CD24^{low} Breast Cancer Stem Cell Isolation Kit (R&D Systems, Minneapolis, MN, USA). Cells were placed in a polystyrene round bottom tube and 25 µl of human CD24 biotinylated antibody was added to the cell suspension and incubated for 15 min at 4°C. The cell pellet was separated by centrifugation and mixed with streptavidin for 15 min at 4°C. The reaction was placed in a MagCelect magnet (R&D systems) for 6 min at room temperature after which the supernatant containing the desired CD24⁻/CD44⁺ breast cancer stem cells were placed in new

tubes. This step was repeated three times. The cells were centrifuged at 300 × g for 8 min, the supernatant was removed, and cells were re-suspended in 0.5 ml of provided buffer and 10 µl human CD44 biotinylated antibody and incubated for 15 min at 4°C, and cells were centrifuged at 300 × g for 8 min. The cell pellet was re-suspended in a buffer with Streptavidin Ferrofluid, mixed gently, incubated for 15 min at 4°C, and the desired CD44^{high} CD24^{low} cell population separated with a MagCelect magnet.

Total RNA isolation. Total RNA was extracted from the CD44⁺/CD24⁺ and CD44⁺/CD24⁻ cell populations isolated from MCF-10A and MDA-MB-231 using the E.Z.N.A.[®] HP Total RNA Kit (Omega Bio-tek[®], Norcross, GA, USA). Cell lysate was passed through a 21-gauge syringe 15-20 times and then transferred to a RNA Homogenizer Mini Column. The column was centrifuged, and the eluate was mixed with 70% ethanol and transferred to a HiBind[®] RNA Mini Column. The RNA was eluted per the protocol from the vendor. The quality and quantity of isolated RNA was measured using Nanodrop Lite spectrophotometer (Thermo Scientific).

Two-step quantitative PCR. Total RNA (2 µg) was converted to cDNA (40 µl) using iScript cDNA Synthesis Kit (Omega Bio-tek, Hercules, CA, USA) according to the manufacturer's protocol. The reaction was carried out in a Perkin-Elmer 9600 Gene Amp PCR System by priming for 5 min at 25°C, reverse transcription for 20 min at 46°C, and incubation for 1 min at 95°C. The cDNA was diluted to a concentration of 5 ng/µl, and stored in aliquots at -20°C. Quantitative PCR (qPCR) was performed by using the StepOnePlus Real-Time PCR System and PowerUp[™] SYBR[™] Green (Applied Biosystems, Foster City, CA, USA). Primers were used to amplify regions that span exon-exon junctions to ensure gene specific amplification. The amplicon sizes for various transcripts ranged from 100 and 500 bp. The following cycling protocol was used: UDG activation at 50°C for 2 min; DNA polymerase activation at 95°C for 2 min; denaturation at 95°C for 15 s, annealing at 60°C for 15s, and extension at 72°C for 1 s for 40 cycles. The relative gene expression was calculated using the $\Delta\Delta C_T$ model (17).

Statistical analysis. Data are expressed as mean±S.E.M., and were analyzed using GraphPad Prism version 8.0 (La Jolla, CA, USA). A one-way analysis of variance (ANOVA) was followed by Tukey Kramer or Sidak's *post-hoc* comparison test. The specific *post-hoc* tests are outlined in figure legends. For all statistical analysis, means were indicated to be statistically different when *p*<0.05.

Results

EPH/ephrin transcript expression profiles in CD44⁺/CD24⁻ cells from non-tumorigenic breast epithelial cells (MCF10A). CD44⁺/CD24⁻ stem-like cells isolated from non-tumorigenic breast epithelial cells (MCF10A) have a unique expression pattern of EPH receptors and ephrin ligands with certain transcripts undetectable under the experimental parameters. Of the 12 EPH receptors and 8 ephrin ligand transcripts profiled, transcripts for EPHA3, EPHA6, EPHA10, and ephrin-A2 were not detectable in MCF10A cells. As shown in Figure 1A, EPHA2 had the highest transcript abundance in CD44⁺/CD24⁻ cells with a mean ΔC_T value of 3.7

Figure 1. Expression pattern of EPH-ephrin transcripts in CD44⁺CD24⁻ cells isolated from a non-tumorigenic breast epithelial cell-line (MCF10A). (A) Box Plot of ΔC_T values ranked in order of decreasing abundance. ΔC_T value of three biological replicates is represented as the mean $\pm$ SD. ΔC_T values were obtained by normalizing EPH-ephrin to PPIA expression. Differences in ΔC_T values between transcripts were measured via two-way ANOVA and Tukey's Post Hoc Multiple Comparisons test: *** $p < 0.001$, ** $p < 0.002$, * $p < 0.03$, $p > 0.01$ (not significant). (B) Amplified EPH receptor electrophoresed on 2.0% agarose gel after 40 cycles of amplification. (C) Amplified ephrin ligands electrophoresed on 2.0% agarose gel after 40 cycles of amplification.

followed by ephrin-A5, ephrin-B2, and ephrin-A1, which had mean ΔC_T values of 5.4, 5.5, and 5.8 respectively. The difference in normalized gene expression between these three transcripts was not significant indicating that these ligands are expressed in relatively equal abundance. EPHB4 was present in the highest abundance. The transcripts for EPHB4

and ephrin-B1 had mean ΔC_T values of 7.6 and 7.4 respectively. The mean ΔC_T for ephrin-A4 was significantly lower than ephrin-A3 and EPHB2, which were expressed in relatively equal abundance. EPHB3 and EPHA1 also showed robust expression in CD44⁺/CD24⁻ cells with mean ΔC_T values of 9.5 and 10.5, respectively. Receptors EPHA1,

EPHA4, EPHA8 were the least expressed transcripts; faint bands for EPHA7 and EPHA4 were visible on agarose gel, whereas EPHA8 was not detectable. Although, qPCR data indicate that EPHA3 is expressed in a very low abundance, a signal was not determined for every technical replicate hence the expression of EPHA3 in MCF10A stem-like cells cannot be confirmed under the experimental parameters used. The overall ranking of EPH/ephrin transcript abundance in the stem-like cells isolated from non-tumorigenic breast epithelial cell is as follows: EPHA2 > ephrin-A5 > (ephrin-A1, ephrin-B2) > (EPHB4, ephrin-B1) > ephrin-A4 > (EPHB2, ephrin-A3) > EPHB3 > EPHA1 > EPHA7 > EPHA4 > EPHA8. A qualitative pattern of expression for various Eph receptors and ephrin ligands in MCF10A stem-like cells is shown in Figures 1B and C.

EPH/ephrin transcript expression profiles in CD44⁺/CD24⁻ cells from invasive triple-negative breast carcinoma cells (MDA-MB-231). As shown in Figure 2A, the CD44⁺/CD24⁻ stem-like cells isolated from invasive, triple-negative breast carcinoma cell line MDA-MB-231 have a distinct expression pattern of EPH/ephrin ligands. Transcripts for EPHA3, EPHA6, and ephrin-A2 were not detectable in this cell-line under the experimental parameters. The transcript for ephrin-A5 was expressed in the highest abundance overall with a mean ΔC_T value of 3.5, EPHA2 was the most robustly expressed A-class receptor with mean ΔC_T value of 5.1, and EPHB2 was the B-class receptor expressed in the highest abundance. However, receptors EPHA8 and EPHB2 were expressed at relatively equal abundance with mean ΔC_T values of 7.9. The abundance of EPHA8 was significantly higher in the stem-like cells isolated from MDA-MB-231 which is in stark contrast to the stem-like cells isolated from MCF10A. Ephrin-B2 was the next highest ranked transcript with a mean ΔC_T value of 8.3. The transcripts for EPHA7, EPHB4, and ephrin-A4 were present in a relatively equal abundance (ΔC_T values 9.2, 9.7, and 9.4, respectively). Signals were also detected for ephrin-A3 (10.3), ephrin-A1 (10.8), ephrin-B1 (11.8), and EPHA4 (12.2). Receptors EPHA1 and EPHB3 were expressed in relatively equal abundance (mean ΔC_T values of 12.9 and 13.0). The least expressed transcript was EPHA10 with mean ΔC_T value of 15.9. According to qPCR data, the relative abundance of EPH/ephrin transcripts in CD44⁺/CD24⁻ cells isolated from invasive MDA-MB-231 is as follows: ephrin-A5 > EPHA2 > (EPHA8, EPHB2) > ephrin-B2 > (EPHA7, EPHB4, ephrin-A4) > ephrin-A3 > ephrin-A1 > (EPHB3, ephrin-B1) > EPHA4 > EPHA1 > EPHA10. A qualitative pattern of expression for various Eph receptors and ephrin ligands in MDA-MB-231 stem-like cells is shown in Figure 2B and C.

Quantitative differences in Eph/ephrin transcripts in CD44⁺/CD24⁻ and CD44⁺/CD24⁺ cells isolated from

MCF10A. There was no significant difference in the ΔC_T values for EPHA4, EPHA5, EPHB2, EPHB3, ephrin-A4, ephrin-B1, ephrin-B2 and ephrin-B3 suggesting that these transcripts are expressed at relatively equal abundance in both the stem-like and differentiated bulk cells. All other transcripts showed significant changes in abundance (Figure 3A). While EPHA1, EPHA7, EPHA8, and ephrin-A5 were all down-regulated in the CD44⁺/CD24⁻ stem-like cell fraction relative to the CD44⁺/CD24⁺ bulk cell fraction, EPHA2, ephrin-A1, and ephrin-A3 were up-regulated (Figure 3C). EPHA8 and ephrin-A3 displayed the greatest differences in expression between the stem-like and bulk cell fractions. Ephrin-A3 was significantly up-regulated by ~20-fold in the stem-like cell fraction. Moreover, EPHA2 as well as its preferred ligand, ephrin-A1, are both comparably up-regulated by 7.0 and 6.0-fold respectively, and EPHA8 was decreased by ~11-fold. In addition, EPHA1, EPHA7, and ephrin-A5 (cognate ligand of EPHA8) were down-regulated in the stem-like cell fraction by 6.8, 8.0, and 6.8-fold respectively (Figure 3E).

Quantitative differences in Eph/ephrin transcripts in CD44⁺/CD24⁻ and CD44⁺/CD24⁺ cells isolated from MDA-MB-231. As shown in Figure 3B, there was a significant difference in normalized gene expression (ΔC_T) between the stem-like and bulk cells for the transcripts corresponding to EPHA2, EPHA4, EPHA7, EPHA8, EPHB2, EPHB3, ephrin-A1, ephrin-A3, and ephrin-A5. All other detectable transcripts were expressed in relatively equal abundance in both the stem-like cells and the bulk cells. Ephrin-A1 was the only transcript down-regulated in the stem-like cell fraction, which was down-regulated by ~4.3-fold (Figure 3D). The transcripts for EPHA2, EPHA4, EPHA7, EPHA8, EPHB2, EPHB3, ephrin-A3, and ephrin-A5 were all up-regulated by ~41, 15, 20, 160, 12, 7, 26, and 3.6-fold respectively (Figure 3F). Similar to MCF-10A, EPHA8 and ephrin-A3 displayed the greatest difference in expression between the stem-like and differentiated cell fractions. However, in contrast both EPHA8 and ephrin-A3 and their preferred binding partners, ephrin-A5 and EPHA4, were also up-regulated in the stem-like cell fraction relative to the differentiated bulk cells (Figure 3F).

Comparative analysis of EPH receptor and ephrin ligand expression in CD44⁺/CD24⁻ cells isolated from normal and carcinoma breast cell-lines. When evaluating the qualitative differences in EPH/ephrin expression in the CD44⁺/CD24⁻ cells isolated from MDA-MB-231 and MCF-10A, EPHA10 was the only transcript that was differentially expressed. EPHA10 was not detectable in MCF10A, but a faint signal was detected in the stem-like cells isolated from MDA-MB-231. The transcripts for EPHA3, EPHA6, and ephrin-A2 were not detectable in both CD44⁺/CD24⁻ and

Figure 2. Expression pattern of EPH-ephrin transcripts in CD44⁺CD24⁻ cells isolated from invasive, triple-negative breast carcinoma cells (MDA-MB-231). (A) Box Plot of ΔC_T values ranked in order of decreasing abundance. ΔC_T value of three biological replicates is represented as the mean $\pm$ SD. ΔC_T values were obtained by normalizing EPH-ephrin to PPIA expression. Differences in ΔC_T values between transcripts were measured via two-way ANOVA and Tukey's Post Hoc Multiple Comparisons test: *** $p < 0.001$, ** $p < 0.002$, * $p < 0.03$, $p > 0.01$ (not significant). (B) Amplified EPH receptor electrophoresed on 2.0% agarose gel after 40 cycles of amplification. (C) Amplified ephrin ligands electrophoresed on 2.0% agarose gel after 40 cycles of amplification.

CD44⁺/CD24⁺ cells isolated from the MDA-MB-231 and MCF10A cell lines (Figure 4A). All other differences in EPH/ephrin transcript expression were quantitative. There was a significant difference in the normalized EPH/ephrin expression (ΔC_T) for the stem-like cell fractions isolated from MDA-MB-231 and MCF10A for all detectable transcripts, with the exception of EPHA2, EPHB2, and ephrin-A4 (Figure 4A). These findings suggest there is a

negligible difference in transcript abundance for EPHA2, EPHB2, and ephrin-A4 in the stem-like cell fractions isolated from these phenotypically distinct cell-lines. The transcripts for EPHA4, EPHA7, EPHA8 and ephrin-A5 were up-regulated in MDA-MB-231 CD44⁺/CD24⁻ cells relative to MCF10A (Figure 4B). EPHA8 was up-regulated by ~486-fold (mean $\Delta \Delta C_T$ of -8.9). Transcripts for EPHA7 and EPHA4 were also up-regulated by ~20.2 and ~12.3-fold with

Figure 3. Comparative analysis of EPH/ephrin expression in CD44⁺/CD24⁻ and CD44⁺/CD24⁺ cells. (A) Box and whisker plot of EPH/ephrin normalized mRNA expression in CD44⁺/CD24⁻ and CD44⁺/CD24⁺ cells from MCF10A. ΔC_T values are represented as the mean $\pm$ SD of three biological replicates. ΔC_T values were obtained by normalizing EPH-ephrin expression by PPIA expression. Differences in ΔC_T values between transcripts were measured via two-way ANOVA and Sidak's Post Hoc Multiple Comparisons test: *** $p < 0.001$, ** $p < 0.002$, * $p < 0.03$, $p > 0.01$ (not significant). (B) Box and whisker plot of EPH/ephrin normalized mRNA expression in CD44⁺/CD24⁻ and CD44⁺/CD24⁺ cells from MDA-MB-231. (C) Stacked Bar graph of $\Delta\Delta C_T$ values ranked in order of decreasing abundance in MCF10A. The mean $\Delta\Delta C_T$ values were calculated by normalizing ΔC_T values the CD44⁺/CD24⁻ stem-like cell fraction relative to the CD44⁺/CD24⁺ differentiated cell fraction isolated from the same cell-line. Negative $\Delta\Delta C_T$ values indicate an up-regulation and positive $\Delta\Delta C_T$ values indicate a down-regulation. (D) Stacked Bar graph of $\Delta\Delta C_T$ values ranked in order of decreasing abundance in MDA-MB-231. (E) Mean fold change for transcripts corresponding to MCF10A. For $\Delta\Delta C_T < 0$, fold change was calculated using the equation $2^{-(\Delta\Delta C_T)}$. For $\Delta\Delta C_T > 0$, fold change was calculated using the equation $-1/2^{-(\Delta\Delta C_T)}$. (F) Mean fold change for transcripts corresponding to MDA-MB-231.

Figure 4. Relative difference in EPH/ephrin expression in CD44⁺CD24⁻ cells isolated from invasive triple-negative breast carcinoma cells (MDA-MB-231) and non-tumorigenic breast epithelial cells (MCF-10A): (A) Box and whisker plot of EPH/ephrin normalized mRNA expression in CD44⁺CD24⁻. ΔC_T values are represented as the mean $\pm$ SD of three biological replicates. ΔC_T values were obtained by normalizing EPH-ephrin expression by PPIA expression. Differences in ΔC_T values between transcripts were measured via two-way ANOVA and Sidak's Post Hoc Multiple Comparisons test: *** $p < 0.001$, ** $p < 0.002$, * $p < 0.03$, $p > 0.01$ (not significant). (B) Stacked Bar graph of $\Delta\Delta C_T$ values ranked in order of decreasing abundance. $\Delta\Delta C_T$ values were calculated by normalizing ΔC_T values for CD44⁺CD24⁻ cells isolated from MDA-MB-231 by the ΔC_T values for CD44⁺CD24⁻ cells isolated from MCF-10A. The mean $\Delta\Delta C_T$ value for each experiment is represented as the mean $\pm$ SD. The differences in $\Delta\Delta C_T$ values between transcripts were measured via two-way ANOVA and Sidak's Post Hoc Multiple Comparisons test: *** $p < 0.001$, ** $p < 0.002$, * $p < 0.03$, $p > 0.01$ (not significant). Negative $\Delta\Delta C_T$ values indicate an up-regulation and positive $\Delta\Delta C_T$ values indicate a down-regulation. (C) Mean fold change for indicated transcripts. For $\Delta\Delta C_T < 0$, fold change was calculated using the equation $2^{-(\Delta\Delta C_T)}$. For $\Delta\Delta C_T > 0$, fold change was calculated using the equation $-1/2^{-(\Delta\Delta C_T)}$.

mean $\Delta\Delta C_T$ of -3.6 and -3.4. Ephrin-A5 was the only ligand that was up-regulated (~6.5-fold; $\Delta\Delta C_T$ of -1.9). Ephrin-A3 was slightly down-regulated by ~2.9-fold (mean $\Delta\Delta C_T$ of 1.5). Transcripts for EPHA1, EPHB3, EPHB4, and ephrin-B2 were down-regulated in the MDA-MB-231 stem cell fraction by approximately 5.8, 2.8, 4.9, 3.9-fold with negligible differences in $\Delta\Delta C_T$ values (2.4, 2.1, 2.0, 2.7). Ephrin-B1 and ephrin-A1 were the most down-regulated transcripts overall. These transcripts were down-regulated by ~27-fold and ~31-fold, respectively (Figure 4C). Therefore, the relative abundance of EPH/ephrin transcripts in MDA-MB-231 relative to MCF10A is as follows: EPHA8 > (EPHA7, EPHA4) > ephrin-A5 > ephrin-A3 > (EPHA1, EPHB3, EPHB4, ephrin-B2) > ephrin-B1 > ephrin-A1.

Discussion

The analysis of EPH/ephrin expression in CD44⁺CD24⁻ stem-like cells isolated from non-tumorigenic (MCF10A) and invasive breast carcinoma (MDA-MB-231) cells revealed that distinctive EPH/ephrin molecular signatures are inherent to each cell line and may contribute to the breast stem-like cell phenotype. As seen in MCF10A, EPH/ephrin expression is stringently regulated in non-tumorigenic mammary stem cells (16) wherein a variety of EPH/ephrin genes associated with tumorigenesis and invasiveness were either not detectable or suppressed in the CD44⁺CD24⁻ fraction. In quiescent stem cells, genes responsible for cell proliferation are often down-regulated, while cell-fate determination genes are frequently up-regulated (18). Thus, the differences in EPH/ephrin expression in CD44⁺CD24⁻ cells isolated from non-tumorigenic and invasive breast epithelial cells lines may contribute to the functional differences in stem-cell proliferation and/or stem-cell quiescence observed in these phenotypically distinct cell-lines.

For instance, the differential expression of ephrin-A1 and ephrin-A5 in the non-tumorigenic and invasive breast carcinoma cell lines was notable. In MCF-10A, ephrin-A1 was up-regulated while ephrin-A5 was down-regulated. Conversely, in MDA-MB-231, ephrin-A1 was down-regulated while ephrin-A5 was up-regulated. These findings are significant in the context of the receptor-ligand pairs, which are up-regulated in the stem-like cells relative to the bulk cells for each cell line. EPHA2 was the only receptor up-regulated in MCF10A, whereas several receptors were up-regulated in MDA-MB-231, including both EPHA2 and EPHA8. The up-regulation of EPHA2 in cancer stem-like cells enhances the self-renewal capacity of the CSC population, whereas ephrin-A1 expression negatively regulates EPHA2-mediated CSC proliferation (19). Therefore, EPHA2/ephrin-A1 forward signaling in MCF10A may contribute to the reduced stem-like cell fraction observed in this cell line. Conversely, the suppression of

ephrin-A1 expression in the MDA-MB-231 stem-like cell fraction facilitates ligand-independent activation of EPHA2, which is associated with increased stem-cell pluripotency (19), and contributes to the increased stem-like cell fraction observed in this cell line.

Moreover, EPHA8 and its cognate ligand ephrin-A5 were up-regulated in MDA-MB-231 and down-regulated in MCF10A. This Eph/ephrin pair appears to influence the stem-like cell dynamics in these cell lines. The systematic comparison of EPH/ephrin transcripts in the CD44⁺/CD24⁻ cells isolated from MDA-MB-231 and MCF10A revealed that receptors EPHA8, EPHA7, EPHA4, and ephrin-A5 were significantly up-regulated in the stem-like cells isolated from invasive breast carcinoma cells. On the other hand, the transcripts for EPHA1, EPHB3, EPHB4, ephrin-A1, ephrin-A3, ephrin-B1 and ephrin-B2 were significantly down-regulated. The down-regulation of EPHB/ephrin-B pairs in MDA-MB-231 cells suggests the involvement of EPHB receptor class in suppressing the BCSC niche. This explanation is supported by the observations indicating the regulation of stem cell proliferation by EPHB/ephrin-B signaling (20), which has been shown to attenuate cell migration and cell differentiation (21). These receptors and ligands have been implicated in activities that regulate the cancer cell communication with tumor-associated monocytes (22), stem/progenitor cell maintenance and cell migration through Rac1 activation (23). In light of our observations with Eph/ephrin profiles of cancer stem cells presented here and reported involvement of these molecules in cancer invasiveness, we postulate that the suppression of EphB receptors, ephrin-B and ephrin-A1 ligands in combination with the upregulation of EPHA8, EPHA7, EPHA4 and ephrin-A5 may contribute to the invasiveness of MDA-MB-231 cells.

Although the role of EPHA8 in cancer stem cells remains elusive, its overexpression correlates to a poor overall survival in other human malignancies, such as epithelial ovarian cancer (EOC) (24-26). In EOC, both EPHA8 and ephrin-A5 are significantly up-regulated (24), while only EPHA8 was reported to be overexpressed in OTSCC and GC (25). In gastric cancer cells, the up-regulation of EPHA8 gene occurs with the up-regulation of the β -catenin gene (27). Wnt/ β -catenin and PI3K/Akt signaling has been shown to promote EMT of gastric cancer cells (28). Interestingly, BCSCs display significantly increased Wnt/ β -catenin signaling relative to the non-tumorigenic bulk cells (29), and the aberrant activity of Wnt/ β -catenin is implicated in the acquisition of the BCSC phenotype (30, 31). Moreover, miR-10a mediates glioma cell migration and invasion by negatively regulating EphA8 to induce EMT (32). Although no data regarding the involvement of EPHA8 signaling in breast cancer stem-like cells is available, it is known to alter the expression of cell-cycle regulatory proteins, matrix metalloproteinases, AKT pathway (26), PI-3 kinase pathway (33), and sustained MAPK activation

(34). Based on significant alteration in EphA8/ephrin-A5 abundance, we hypothesize that either EPHA8 mediates cancer stem cells transition from quiescent to proliferative state in the milieu of MDA-MB-231 environment or alternatively its constitutive expression in stem cells transforms stem cells as well as the bulk cells. Overall, our observations support previously reported data regarding the role of the EPH/ephrin in modulating stem-cell behavior (35), and contribute to our current understanding of how the altered expression of the EPH/ephrin gene family may influence the distinct functional and cellular phenotypes of breast cancer. In particular, the established role of EphA8/ephrin-A5 in facilitating PI3 Kinase-Akt-MAP kinase axis points to a probable interaction of cancer stem cells and bulk cancer cells to determine the overall phenotype of breast tumors.

Conflicts of Interest

The Authors declare no conflicts of interest.

Authors' Contributions

ML designed/executed the experiments, analyzed the data and wrote the manuscript; JT, JS, SS and BJ contributed to preliminary experiments of cell culture, cell isolation, and RT-PCR; RPK served as PI, designed the project/experiments, supervised the overall project and wrote the manuscript.

Acknowledgements

The Authors wish to thank our colleagues for making their facilities available from time to time.
